We propose a validity preserving translation from a subset of epistemic Alternating-time Temporal Logic (ATL) to epistemic Computation Tree Logic (CTL). The considered subset of epistemic ATL is known to have the finite model property and decidable model-checking. This entails the decidability of validity but the implied algorithm is unfeasible. Reducing the validity problem to that in a corresponding system of CTL makes the techniques for automated deduction for that logic available for the handling of the apparently more complex system of ATL.

Introduction

The strategic cooperation modalities of alternating time temporal logic (ATL, [AHK97, AHK02]) generalize the path quantifier $\forall$ of computation tree logic (CTL). Combinations of ATL with modal logics of knowledge [vdHW03, JvdH04] extend temporal logics of knowledge (cf. e.g. [FHMV95]) in the way ATL extends CTL. Automated deduction for CTL and linear time epistemic temporal logics has been studied extensively [FDP01, BDF99, GS09a, GS09b]. There is much less work on the topic for ATL, and hardly any for its epistemic extensions. The decidability of validity in ATL with complete information was established in [GvD06] as a consequence of the finite model property, where the completeness of a Hilbert-style proof system was given too. Hilbert-style proof systems are known to be unsuitable for automating proof search. The situation was remedied by a tableau-based decision procedure developed in [GS09c]. Along with that, the same authors developed tableau systems for branching epistemic temporal logics in [GS09b]. Temporal resolution (cf. e.g. [FDP01]), which is well understood for linear time logics and their epistemic extensions, was considered for ATL in [Zha10], but only for the $\langle\langle,\rangle\rangle$-subset, which is similar to coalition logic [Pau02] and enables only reasoning about a fixed number of steps. To our knowledge, no similar work has been done for systems epistemic ATL.

In this paper we continue the study [GDE11] of a system of ATL with the operator of distributed knowledge under the perfect recall assumption. In [GDE11] we established the finite model property for a subset, and a model-checking algorithm for the whole system. That algorithm assumed that coalition members can use the distributed knowledge of their coalitions to guide their actions. Dropping that assumption is known to render model-checking undecidable [DT11]. As expected, the validity-checking algorithm which these results imply is unfeasible.

In this paper we propose a validity preserving translation from another subset of that logic into epistemic CTL, with distributed knowledge and perfect recall again. As it becomes clear below, the need to consider a subset appears to be due to the lack of connectives in epistemic CTL to capture some interactions between knowledge and the progress of time. The translation makes no assumption on coordination within coalitions and there is no dependence on the availability of the past temporal modalities which
are featured in the axiomatization from \cite{GDE11}. A semantic assumption that we keep is finite branching: only finitely many states should be reachable in one step from any state and models should have only finitely many initial states. Dropping that assumption would disable the fixpoint characterization of \((U, U)\)-objectives that we exploit, because of the requirement on strategies to be uniform. The translation enables the use of the known techniques for mechanized proof in the apparently simpler logic CTL and its epistemic extensions \cite{BF99,GS09b}. Building on our previous work \cite{GDE11}, we work with the semantics of ATL on interpreted systems in their form adopted in \cite{LR06}.

1 Preliminaries

1.1 Propositional epistemic ATL with perfect recall (ATL\(_D^{IR}\))

The syntax of ATL\(_D^{IR}\) formulas can be given by the BNF
\[
\varphi, \psi ::= \bot \mid p \mid (\varphi \Rightarrow \psi) \mid (t \Gamma) \varphi \mid (\langle \Gamma \rangle) \varphi \mid \langle \Gamma \rangle \psi \mid [\Gamma](\varphi \cup \psi)
\]
Here \(\Gamma\) ranges over finite sets of agents, and \(p\) ranges over propositional variables. In this paper we exclude the past temporal operators as their presence does not affect the working of our translation.

An interpreted system is defined with respect to some given finite set \(\Sigma = \{1, \ldots, N\}\) of agents, and a set of propositional variables (atomic propositions) \(AP\). There is also an environment \(e \notin \Sigma\); in the sequel we write \(\Sigma_e\) for \(\Sigma \cup \{e\}\).

**Definition 1 (interpreted systems)** An interpreted system for \(\Sigma\) and \(AP\) is a tuple of the form
\[
\langle L_i : i \in \Sigma_e, I, \langle Act_i : i \in \Sigma_e \rangle, t, V \rangle
\]
where:
- \(L_i, i \in \Sigma_e\), are nonempty sets of local states; \(L_\Gamma\) stands for \(\prod_{i \in \Gamma} L_i, \Gamma \subseteq \Sigma_e\);
- elements of \(L_{\Sigma_e}\) are called global states;
- \(I \subseteq L_{\Sigma_e}\) is a nonempty set of initial global states;
- \(Act_i, i \in \Sigma_e\), are nonempty sets of actions; \(Act_\Gamma\) stands for \(\prod_{i \in \Gamma} Act_i\);
- \(t : L_{\Sigma_e} \times Act_{\Sigma_e} \rightarrow L_{\Sigma_e}\) is a transition function;
- \(V \subseteq L_{\Sigma_e} \times AP\) is a valuation of the atomic propositions.

For every \(i \in \Sigma_e\) and \(l', l'' \in L_{\Sigma_e}\) such that \(l'_i = l''_i\) and \(l'_e = l''_e\) the function \(t\) satisfies \((t(l', a))_i = (t(l'', a))_i\).

In the literature an interpreted system also includes a protocol to specify the actions which are permitted at every particular state. Protocols are not essential to our study here as the effect of a prohibited action can be set to that of some fixed permitted action (which is always supposed to exist) to produce an equivalent system in which all actions are always permitted. Our variant of interpreted systems is borrowed from \cite{LR06} and has a technically convenient feature which is not present in other works \cite{FHMV95,LQR}: every agent’s next local state can be directly affected by the local state of the environment through the transition function. Here follow the technical notions that are relevant to satisfaction of ATL formulas on interpreted systems.

**Definition 2 (global runs and local runs)** Given an \(n \leq \omega\), a run of length \(n\) is a sequence
\[
r = l_0, a_0 l_1, a_1 \ldots l_n, (Act_L, L_L)^n
\]
such that \(l_0 \in I\) and \(l_{j+1} = t(l_j, a_j)\) for all \(j < n\). A run is infinite, if \(n = \omega\); otherwise it is finite. In either case we write \(|r|\) for the length \(n\) of \(r\). (Note that a run of length \(n < \omega\) is indeed a sequence of \(2n + 1\) states and actions.)
Given \( r \) as above and \( \Gamma \subseteq \Sigma \), we write \( r_\Gamma \) for the corresponding local run
\[
0^1 a^0 \ldots a^{i-1} l^i \in L_\Gamma(Act_\Gamma L_\Gamma)^n
\]
of \( \Gamma \) in which \( l^i = \{ l^i : i \in \Gamma \} \) and \( a^i = \{ a^i : i \in \Gamma \} \).

We denote the set of all runs of some fixed length \( n \leq \omega \), the set of all finite runs, and the set of all runs in \( IS \) by \( R^n(\IS) \), \( R^{\omega n}(\IS) \) and \( R(\IS) \), respectively.

Given \( i, j < \omega \) and an \( r \) as above such that \( i \leq j \leq |r| \), we write \( r[i..j] \) for \( l^i a^i \ldots a^{j-1} l^j \).

**Definition 3 (indiscernibility)** Given \( r', r'' \in R(\IS) \) and \( i \leq |r'|, |r''| \), we write \( r' \sim_{\Gamma,i} r'' \) if \( r'[0..i]_\Gamma = r''[0..i]_\Gamma \). We write \( r' \sim_{\Gamma} r'' \) for the conjunction of \( r' \sim_{\Gamma,0} r'' \) and \( |r'| = |r''| \).

Sequences of the form \( r_0 \) consist of \( \langle s \rangle \)'s, and, consequently, \( [r]_\varnothing \) is the class of all the runs of length \( |r| \). Obviously \( \sim_{\Gamma,0} \) and \( \sim_{\Gamma} \) are equivalence relations on \( R(\IS) \).

**Definition 4** We denote \( \{ r' \in R(\IS) : r' \sim_{\Gamma} r \} \) by \( [r]_\Gamma \).

**Definition 5 (coalition strategies)** A strategy for \( \Gamma \subseteq \Sigma \) is a vector \( s = \langle s_i : i \in \Gamma \rangle \) of functions \( s_i \) of type \( \{ r_i : r \in R^\omega(\IS) \} \rightarrow Act_i \). We write \( \Sigma(\IS, \Gamma) \) for the set of all the strategies for \( \Gamma \) in the considered interpreted system \( \IS \). Given \( s \in \Sigma(\IS, \Gamma) \) and \( r \in R^{\omega n}(\IS) \), we write \( \text{out}(r, s) \) for the set
\[
\{ r' = 0^1 a^0 \ldots a^{n-1} l^n \in R^\omega(\IS) : r'[0..n] = r, a^i = s_i(r[0..i], r) \text{ for all } i \in \Gamma \text{ and } j \geq |r| \}
\]
of the outcomes of \( r \) when \( \Gamma \) sticks to \( s \) from step \( |r| \) on. Given an \( X \subseteq R^{\omega n}(\IS) \), \( \text{out}(X, s) = \bigcup_{r \in X} \text{out}(r, s) \).

Strategies, as defined above, are determined by the local views of the considered coalition members and are therefore uniform.

**Definition 6 (modelling relation of \( ATL_{\text{ih}}^D \))** The relation \( IS, r \models \varphi \) is defined for \( r \in R^{\omega n}(\IS) \) and formulas \( \varphi \) by the clauses:
- \( IS, r \not\models \bot \);
- \( IS, r \models \varphi \Rightarrow \psi \) if either \( IS, r \not\models \varphi \) or \( IS, r \models \psi \);
- \( IS, r \models \text{Dr}_\Gamma \varphi \) if \( IS, r' \models \varphi \) for all \( r' \in [r]_\Gamma \);
- \( IS, r \models \langle \Gamma \rangle \varphi \) if there exists an \( s \in \Sigma(\IS, \Gamma) \) such that
  \[
  IS, r'[0..|r| + 1] \models \varphi \text{ for all } r' \in \text{out}(r, \Gamma, s);
  \]
- \( IS, r \models \text{[\Gamma]}(\varphi \cup \psi) \) if there exists an \( s \in \Sigma(\IS, \Gamma) \) s. t. for every \( r' \in \text{out}(r, \Gamma, s) \) there exists a \( k < \omega \) s. t. \( IS, r'[0..|r| + i] \models \varphi \) for all \( i < k \) and \( IS, r'[0..|r| + k] \models \psi \);
- \( IS, r \models \text{[[\Gamma]]}(\varphi \cup \psi) \) if for every \( s \in \Sigma(\IS, \Gamma) \) there exist an \( r' \in \text{out}(r, \Gamma, s) \) and a \( k < \omega \) s. t.
  \[
  IS, r'[0..|r| + i] \models \varphi \text{ for all } i < k \text{ and } IS, r'[0..|r| + k] \models \psi.
  \]

Validity of formulas in entire interpreted systems and on the class of all interpreted systems, that is, in the logic \( ATL_{\text{ih}}^D \), is defined as satisfaction at all 0-length runs in the considered interpreted system, and at all the 0-length runs in all the systems in the considered class, respectively.

In this paper we assume that each coalition member uses only its own observation power in following a coalition strategy. Allowing coalition members to share their observations gives rise to a more general form of strategy, which are functions of type \( \{ r \Gamma : r \in R^{\omega n}(\IS) \} \rightarrow Act_\Gamma \), and which was assumed by the model-checking algorithm proposed in [GDE+[1]].
Abbreviations

\(\top, \neg, \lor, \land\) and \(\iff\) have their usual meanings. To keep the use of \(\{\) and \(\}\) down, we assume that unary connectives bind the strongest, the binary modalities \(\langle\![\Gamma]\rangle\!(U)\) and \(\llbracket\!\Gamma\!\rrbracket\!(U)\), and the derived ones below, bind the weakest, and their parentheses are never omitted, and the binary boolean connectives come in the middle, in decreasing order of their binding power as follows: \(\land, \lor, \Rightarrow \) and \(\iff\). We enumerate coalitions without the \(\{\) and \(\}\). E.g., the shortest way to write \(\langle\![\{1\}\rangle\!(p \Rightarrow q) \land P_{\{1\}}r \land UD_{\{2,3\}}(r \lor q)\rangle\!\) is \(\langle\![1\]\rangle\!(p \Rightarrow q) \land P_1r \land UD_{2,3}(r \lor q)\). We write \(P\) for the dual of \(D\):

\[
P_1\varphi \equiv \neg D_1\neg\varphi.
\]

The rest of the combinations of the cooperation modality and future temporal connectives are defined by the clauses

\[
\langle\![\Gamma]\rangle\!(\top U\varphi) = \langle\![\Gamma]\rangle\!\varphi \lor \langle\![\Gamma]\rangle\!(\varphi W\psi) = \neg\langle\![\Gamma]\rangle\!(\neg\psi U\neg\psi \land \neg\varphi)\]
\[
\langle\![\Gamma]\rangle\!(\top U\varphi) = \langle\![\Gamma]\rangle\!\varphi \lor \langle\![\Gamma]\rangle\!(\varphi W\psi) = \neg\langle\![\Gamma]\rangle\!(\neg\psi U\neg\psi \land \neg\varphi)
\]

1.2 \(ATL_{DR}^D\) with epistemic objectives only

In [GDE11] we axiomatized a subset of \(ATL_{DR}^D\) with past in which \(\langle\!\langle .\rangle\!\rangle\!(U)\) was allowed only in the derived construct \(\langle\![\Gamma]\rangle\!(\top U\varphi)\), and \(\llbracket\!\cdot\!\rrbracket\!(U)\) was allowed only in the derived construct \(\langle\![\Gamma]\rangle\!(\top U\varphi)\). Because of the validity of the equivalences

\[
\langle\![\Gamma]\rangle\!(\top U\varphi) \iff \langle\![\Gamma]\rangle\!(\varphi W\psi) \iff \langle\![\Gamma]\rangle\!(\varphi W\psi)
\]

that entailed that all the objectives allowed in that subset were epistemic. We argued that, under some assumptions, any \(\langle\!\langle \cdot\rangle\!\rangle\!(U)\) formula could be transformed into an equivalent one of the form \(\langle\![\Gamma]\rangle\!(\varphi W\psi)\) thus asserting the significance of the considered subset. Both the axiomatization and the reduction to epistemic goals relied on the presence of the past operators. In this paper we consider another subset of \(ATL_{DR}^D\). Its formulas have the syntax

\[
\varphi, \psi ::= \bot \mid p \mid (\varphi \Rightarrow \psi) \mid D_1\varphi \mid \langle\![\Gamma]\rangle\!(\varphi W\psi) \mid \langle\![\Gamma]\rangle\!(\varphi W\psi)
\]

Unlike the subset from [GDE11], here we allow formulas of the form \(\langle\![\Gamma]\rangle\!(D_1\varphi UD_1\psi)\). However, we exclude even the special case \(\langle\![\Gamma]\rangle\!(\top U\varphi)\) of the use of \(\llbracket\!\cdot\!\rrbracket\!(D_1\varphi UD_1\psi)\). The reasons are discussed in the end of Section 2.

1.3 \(CTL\) with distributed knowledge

This is the target logic of our translation. Its formulas have the syntax

\[
\varphi, \psi ::= \bot \mid p \mid (\varphi \Rightarrow \psi) \mid D_1\varphi \mid \exists\circ\varphi \mid \exists(\varphi U\psi) \mid \forall(\varphi U\psi)
\]

where \(\Gamma\) ranges over finite alphabets of agents as above. The clauses for the semantics of the connectives in common with \(ATL_{DR}^D\) and \(ATL_{DR}^D\) are the same, except for the new connective \(\exists\circ\varphi\) for expressing that there is at least one agent that is willing to accept all goals of \(\varphi\) in all future steps. The clauses about formulas built using \(\exists\) and \(\forall\) are as follows:

\[
\begin{align*}
&IS, r \models \exists\circ\varphi \quad \text{iff} \quad \text{there exists an } r' \in R^{\mid r\mid+1}(IS) \text{ such that } r = r'[0..\mid r\mid] \text{ and } IS, r' \models \varphi; \\
&IS, r \models \exists(\varphi U\psi) \quad \text{iff} \quad \text{there exists an } r' \in R^\omega(IS) \text{ such that } r = r'[0..\mid r\mid] \text{ and a } k < \omega \\
&\quad \text{such that } IS, r'[0..\mid r\mid + i] \models \psi \\
&\quad \text{for all } i < k \text{ and } IS, r'[0..\mid r\mid + k] \models \psi;
\end{align*}
\]

Note that the occurrences of \(D_0\) in the definitions of the equivalences are important for the validity of the equivalences

\[
P_0\exists\circ\varphi \iff \llbracket\!\emptyset\!\rrbracket\!(\top U\varphi), \quad P_0\exists(\varphi U\psi) \iff \llbracket\!\emptyset\!\rrbracket\!(\varphi U\psi) \text{ and } D_0\forall(\varphi U\psi) \iff \langle\![\emptyset]\rangle\!(\varphi U\psi).
\]
in the combined language of $\text{ATL}_{\text{DR}}^0$ and $\text{CTL}$ because of the requirement on strategies to be uniform; e.g., $\langle \{\emptyset\} \rangle (\varphi U \psi)$ means that $(\varphi U \psi)$ holds along all the extensions of all the runs which are indiscernible from the reference run to the empty coalition. Therefore here $\langle \{\emptyset\} \rangle$ does not subsume $\forall$ in the straightforward way known about the case $\text{ATL}$ of complete information.

The combination $\forall \circ$ and the combinations of $\exists$ and $\forall$ with the derived temporal connectives ($\omega$), $\diamond$ and $\square$ are defined in the usual way.

2 A validity preserving translation into $\text{CTL} + \mathcal{D}$ with perfect recall

Our translation captures the subset of $\text{ATL}$ which is given by the BNF

$$\varphi, \psi ::= \bot | \varphi \lor \psi | \diamond \varphi | (\varphi \square \psi) | D_r \varphi | \langle\langle \Gamma \rangle \rangle \circ \varphi | \langle\langle \Gamma \rangle \rangle (D_r \varphi \sqcup \psi)$$

We explain how to eliminate occurrences of $\langle\langle \cdot \rangle \rangle$ in formulas of the form $\langle\langle \Gamma \rangle \rangle (D_r \varphi \sqcup \psi)$ first. In the sequel we write $[\alpha/p]\beta$ for the substitution of the occurrences of atomic proposition $p$ in $\beta$ by $\alpha$.

**Proposition 7** Assuming that $p$ and $q$ are fresh atomic propositions, the satisfiability of

$$\langle\langle \Gamma \rangle \rangle (D_r \varphi \sqcup \psi)/p \chi$$

(at a 0-length run) is equivalent to the satisfiability of

$$\chi \wedge D_r \forall (\forall \varphi \lor \exists q \Rightarrow D_r \varphi \land \langle\langle \Gamma \rangle \rangle (\forall q \Rightarrow p))$$

Next we explain how to eliminate occurrences of the "basic" $\text{ATL}$ construct $\langle\langle \Gamma \rangle \rangle \circ \varphi$. Let $\text{IS}$ stand for some arbitrary interpreted system ($\mathcal{I}$) with finite branching, with $\Sigma = \{1, \ldots, N\}$ as its set of agents, $\mathcal{AP}$ as its vocabulary. We adapt the following simple observation, which works in case $\text{Act}_i$, $i \in \Sigma$ are fixed.

Readers who are familiar with the original semantics of $\text{ATL}$ on alternating transition systems (ATS) from [AHK97] will recognize the similarity of our technique with the transformation of concurrent game structures into equivalent ATS from [GJ04]. Assuming that $\text{Act}_i$, $i \in \Sigma_e$, are pairwise disjoint, and disjoint with $\mathcal{AP}$, we consider the vocabulary $\mathcal{AP}^{\text{Act}} = \mathcal{AP} \cup \bigcup_{i \in \Sigma_e} \text{Act}_i$.

**Definition 8** Given $\text{IS}$ and $\ast \notin \bigcup_{i \in \Sigma_e} \text{Act}_i$, we define the interpreted system

$$\text{IS}^{\text{Act}} = \langle\langle L^\text{Act}_i : i \in \Sigma_e \rangle, r^\text{Act}, (\text{Act}_i : i \in \Sigma_e), t^\text{Act}, V^\text{Act} \rangle$$

by putting:

$$L^\text{Act}_i = L_i \times (\text{Act}_i \cup \{\ast\}), i \in \Sigma_e;$$

$$r^\text{Act} = \langle\langle \{l_i, a_i : i \in \Sigma_e : l \in I\} \rangle;$$

$$t^\text{Act}(\langle\langle \{l_i, a_i : i \in \Sigma_e \rangle, b \rangle = \langle\langle \{t(l, b_i) : i \in \Sigma_e \rangle;$$

$$V^\text{Act}(\langle\langle \{l_i, a_i : i \in \Sigma_e \rangle, p \rangle = V(\langle\langle l_i, : i \in \Sigma_e \rangle, p) \text{ for } p \in \mathcal{AP};$$

$$V^\text{Act}(\langle\langle \{l_i, a_i : i \in \Sigma_e \rangle, b \rangle = b = a_j \text{ for } b \in \text{Act}_j, j \in \Sigma_e.$$

In short, an $\text{IS}^{\text{Act}}$ state is an $\text{IS}$ state augmented with a record of the actions which lead to it, the dummy symbol $\ast$ being used in initial states. Let $R \subseteq L^\text{Act}_0 \times L^\text{Act}_{\text{fin}}$ and $R(\langle\langle \{l_i, a_i : i \in \Sigma_e \rangle, \{v(l, b_i) : i \in \Sigma_e \rangle \text{ iff } v = t^\text{Act}(l, b).$ Then $\text{IS}^{\text{Act}}, r \models \exists \circ \varphi$ iff $\text{IS}^{\text{Act}}, r a_1 l' \models \varphi$ for some $l' \in R(l)$ and the only $a \in \text{Act}_{\Sigma_e}$ such that $r a l' \in R(l) (\text{IS}^{\text{Act}}).$ The key observation in our approach is that

$$\text{IS}, r \models \langle\langle \{i_1, \ldots, i_k\} \rangle \circ \varphi \text{ iff } \text{IS}^{\text{Act}}, r^{\text{Act}} \models \bigwedge_{a_i \in \text{Act}_{i_1}} \ldots \bigwedge_{a_k \in \text{Act}_{i_k}} D_{\{i_1, \ldots, i_k\}} \forall (\bigwedge_{j=1}^{k} a_{i_j} \Rightarrow \varphi)$$
For this observation to work without referring to the actions in the particular interpreted system, given an arbitrary IS, we enrich it with dedicated actions which are linked to the objectives occurring in the considered formula. We define the transition function on these actions so that if a particular $\diamond \varphi$-objective can be achieved at finite run $r$ at all, then it can be achieved by taking the corresponding dedicated actions at the last state of $r$. This can be achieved in forest-like systems where runs can be determined from their final states. Similarly, we introduce express actions for the environment that enable it to foil objectives at states at which they objectives cannot be achieved by the respective coalitions using any strategy based on the original actions. (Giving the environment such powers does not affect the satisfaction of formulas as it never participates in coalitions.) The sets $\text{Act}_i$, $i \in \Sigma_e$ of atomic propositions by which we model actions satisfy the formula

$$A(\text{Act}_1, \ldots, \text{Act}_N, \text{Act}_e) = \bigwedge_{a_i \in \text{Act}_1} \ldots \bigwedge_{a_N \in \text{Act}_N} \bigwedge_{a_e \in \text{Act}_e} \exists a_i,$$

which states that any vector of actions from $\text{Act}_N$ produces a transition. Consider an $\text{ATL}^0_{\text{IR}}$ formula of the form below with no occurrences of $(U,.)$-objectives:

$$\chi \land \Delta \varphi \forall \bigwedge \bigwedge \exists \bigwedge \bigwedge \bigwedge \text{Act}(\text{Act}_1, \ldots, \text{Act}_N, \text{Act}_e)$$

(5)

Here $\text{Act}_1, \ldots, \text{Act}_N, \text{Act}_e$ consist of the atomic propositions which have been introduced to eliminate $\langle \langle \Gamma \rangle \rangle \circ \varphi$-subformulas so far. For the original $\chi$ we assume $\text{Act}_i = \{ \text{nop} \}$, $i \in \Sigma_e$, where nop have no specified effect. We remove the occurrences of $\langle \langle \Gamma \rangle \rangle \circ \varphi$-subformulas in $\chi$ working bottom-up as follows.

**Proposition 9** Let $\varphi$ $i \in \Gamma \cup \{ e \}$, be fresh atomic propositions, $\text{Act}_i = \text{Act}_i \cup \{ \varphi \}$ for $i \in \Sigma \cup \{ e \}$ and $\text{Act}_e = \text{Act}_e$ for $i \in \Sigma \setminus \Gamma$. Then the satisfiability of

$$\langle \langle \Gamma \rangle \rangle \circ \varphi / p \chi \land \Delta \varphi \forall \bigwedge \bigwedge \exists \bigwedge \bigwedge \bigwedge \text{Act}(\text{Act}_1, \ldots, \text{Act}_N, \text{Act}_e)$$

entails the satisfiability of the formula

$$\left[ \Delta \varphi \bigwedge \left( \bigwedge_{i \in \Gamma} \varphi \Rightarrow \varphi \right) / p \right] \chi \land \left[ \Delta \varphi \bigwedge \Delta \varphi \bigwedge \left( \bigwedge_{i \in \Gamma} \varphi \Rightarrow \varphi \right) \lor \varphi \lor \varphi \lor \left( \varphi \Rightarrow \varphi \right) \right]$$

(7)

The above proposition shows how to eliminate one by one all the occurrences of the cooperation modalities in an any given $\text{ATL}^0_{\text{IR}}$ formula $\chi$ with the cooperation modalities appearing only in subformulas of the form $\langle \langle \Gamma \rangle \rangle \circ \varphi$ and obtain a $\text{CTL} + \text{D}$ formula $\varphi'$ such that if $\chi$ is satisfiable, then so is $\chi'$. Now consider a purely-$\text{CTL} + \text{D}$ formula of the form (5). The satisfaction of (5) requires just a transition relation for the passage of time to define as it contains no $\langle \langle \Gamma \rangle \rangle$'s and hence no reference to actions. That is, we assume a satisfying model of the form

$$IS^- = \langle L_i : i \in \Sigma_e \rangle, I, -, V \rangle$$

(8)

where $L_i, i \in \Sigma_e, I$ and $V$ are as in interpreted systems, and $-$ is a serial binary relation on the set of the global states $L_\Sigma$ that represents the passage of time. We define the remaining interpreted system components as follows. We choose the set of actions of each agent $i$, including the environment, to be the corresponding set of atomic propositions $\text{Act}_i$ from (5). For any $a \in \text{Act}_\Sigma$, and any $l \in L_\Sigma$, we choose $t(l, a)$ to be an arbitrary member of $\{ l' \in L_\Sigma : V(l', a_i) \}$. The nonemptiness of the latter set is guaranteed by the validity of $A(\text{Act}_1, \ldots, \text{Act}_N, \text{Act}_e)$ in $IS^-$, which states that every state has a successor.
satisfying the conjunction $\bigwedge_{i} a_i$ for any given vector of actions $a \in \text{Act}_{\Sigma}$. Let $IS$ stand for the system obtained by this definition of $\text{Act}_i$, $i \in \Sigma_e$, and $t$. It remains to show that

$$ IS, r \models D_T \forall \left( \bigwedge_{i \in \Gamma} a_{\Gamma,i} \Rightarrow \varphi \right) \tag{9} $$

is equivalent to $IS, r \models \langle \Gamma \rangle \circ \varphi$ for any subformula $\langle \Gamma \rangle \circ \varphi$ eliminated in the process of obtaining (5). For the forward direction, establishing that the actions $a_{\Gamma,i} \varphi$, $i \in \Gamma$ provides $\Gamma$ with a strategy to achieve $\varphi$ in one step is easily done by a direct check. For the converse direction, if (9) is false, then the validity of the second conjunctive member of (7) entails that $\Gamma$ cannot rule out the possibility that the environment can enforce $\neg \varphi$ in one step by choosing its corresponding action $a_{\Gamma,e} \varphi$.

**Formulas of the form $\llbracket \Gamma \rrbracket (P_T \varphi \cup P_T \psi)$**

We first note that no restriction on formulas of the respective more general form $\llbracket \Gamma \rrbracket (\varphi \cup \psi)$ is necessary in the case of complete information.

**Proposition 10 (eliminating $\llbracket \Gamma \rrbracket (\varphi \cup \psi)$ in ATL with complete information)** Let $p$ and $q$ be some fresh atomic propositions. The satisfiability of

$$ \llbracket \llbracket \Gamma \rrbracket (\varphi \cup \psi) \rrbracket /p \chi $$

in ATL with complete information is equivalent to the satisfiability of

$$ \chi \wedge \forall \Box (p \lor q) \Rightarrow \psi \lor (\varphi \land \llbracket \Gamma \rrbracket \circ q)) \tag{10} $$

In the incomplete information case our approach suggests replacing $\llbracket \llbracket \Gamma \rrbracket (P_T \varphi \cup P_T \psi) /p \chi$ by

$$ \chi \wedge D_q \forall \Box (p \lor q) \Rightarrow P_T \psi \lor (P_T \varphi \land \llbracket \Gamma \rrbracket \circ q)) $$

where, in a forest-like system $IS$, $q$ is supposed to mark states which are reached from runs $r$ in which $\Gamma$ cannot achieve $\langle P_T \varphi \cup P_T \psi \rangle$ when $\Gamma$’s actions $a$ are complemented on behalf of the non-members of $\Gamma$ by some actions $b_{a_1,r}$, that foil the objective, and ... is supposed to express that any sequence of vectors of actions $a_1,a_2,... \in \text{Act}_T$ when complemented by the corresponding $b_{a_1,r_1}, b_{a_2,r_2},...$ can generate a sequence $r_1,r_2,...$ of finite runs, starting with the reference one, each of them being $\Gamma$-indiscernible from the extension of the previous one, by the outcome of the respective $a_k\cdot b_{a_k,r_k}$, such that there exists a $k < \omega$ with $IS, r_j \models q \land D_T \varphi$, $j = 1,...,k - 1$, and $IS, r_k \models \neg q \lor D_T \psi$. The fixpoint construct that would best serve expressing this condition can be written as $\mu X. \alpha \lor (\beta \land P_T \forall \Box X)$ in the modal $\mu$-calculus (cf. e.g. [BS06]). Finding a substitute for it in $CTL + D$ appears problematic.

**Concluding remarks**

Our approach is inspired by temporal resolution [FDP01], which has been extended to epistemic $LTL$ [DFW98] and to (non-epistemic) $CTL$ and $CTL^*$ [BF99, BDF99], the latter system being the closest to our target system $CTL + D$. Following the example of these works, a resolution system for $CTL + D$ could be proved complete by showing how to reproduce in it any proof in some complete, e.g., Hilbert
style proof system. A complete axiomatization for epistemic $CTL^*$ with perfect recall can be found in [vdMK03], but the completeness was demonstrated with respect to the so-called bundle semantics, where a model may consist of some set of runs that need not be all the runs generated by a transition system. and the form of collective knowledge considered in [vdMK03] is common knowledge, whereas we have distributed knowledge. The setting for the complexity results from [HV86] is similar. The tableau-based decision procedure for epistemic $CTL$ with both common and distributed knowledge from [GS09b] does not cover the case of perfect recall. To the best of our knowledge no decision procedure of feasible complexity such as the resolution- and tableau-based ones that are available for so many closely related systems from the above works has been developed yet for validity in $CTL + D$ with perfect recall.
