GWI in deterministic environment

Stationary distribution – existence

Theorem (Quine (1970), Foster & Williamson (1971))

Unique stationary distribution exists iff

$$\int_0^1 \frac{1 - \mathbf{E}s^B}{\mathbf{E}s^A - s} \mathrm{d}s < \infty.$$

$$X_\infty = B_1 + \theta_1 \circ B_2 + \theta_1 \circ \theta_2 \circ B_3 + \ldots = \sum_{i=0}^\infty \Pi_i \circ B_{i+1}.$$

If $m = \mathbf{E}A < 1$, then $\mathbf{E}\log B < \infty$ is necessary and sufficient.
If $m = 1$, then the condition holds if $\mathbf{P}(A > n) \sim \ell_A(n)n^{-1-\alpha}$,
$\mathbf{E}B < \infty$, $\alpha \in (0,1)$, or $\mathbf{P}(B > n) \sim \ell_B(n)n^{-\beta}$, $\beta > \alpha$.

GWI in deterministic environment

Critical case, $m = 1$

Theorem (Guo & Hong (2024))

Assume $\mathbf{P}(A > n) \sim \ell_A(n)n^{-1-\alpha}$, $\alpha \in (0, 1)$,
$\mathbf{P}(B > n) \sim \ell_B(n)n^{-\beta}$, $\beta > \alpha$, additional assumption on ℓ_A, ℓ_B.
Then

$$\mathbf{P}(X_\infty > x) \sim \ell(x)x^{-(\beta-\alpha)}.$$

Without immigration: Fleischmann & Vatutin & Wachtel (2008):
$\mathbf{P}(W > n) \sim \ell(n)\, n^{-1/(1+\alpha)}$, W: total progeny
Borovkov & Vatutin (1996): $\mathbf{P}(M > x) \sim \frac{\alpha}{x}$

GWI in deterministic environment

Critical case, $m = 1$

Assume $\mathbf{P}(A > n) \sim \ell_A(n) n^{-1-\alpha}$, $\alpha \in (0, 1)$, $\mathbf{E}B < \infty$.
K & Kubatovics (2025+, work in progress):

$$\mathbf{P}(X_\infty > x) \sim \ell(x) x^{-(1-\alpha)}.$$

Stationary chain $(X_n)_{n \geq 0}$ is regularly varying, tail process:

$$\mathcal{L}\left((X_n/x)|X_0 > x\right) \longrightarrow Y(1, 1, \ldots),$$

$\mathbf{P}(Y > y) = y^{-(1-\alpha)}$. Extremal index $= 0$. The anticlustering condition does not hold.
Explicit calculations are possible: Alsmeyer & Hoang (2025):
Power fractional distributions, Lindo & Sagitov (2016):
θ-branching

Stable limit for partial sums

Theorem (Basrak & K 2022)

Let $b_n = 0$, $\kappa < 1$, $b_n = n\mathbf{E}(X_\infty/a_n I(X_\infty \leq a_n))$, $\kappa \in [1, 2)$. Then

$$V_n = \sum_{k=1}^{n} \frac{X_k}{a_n} - b_n \xrightarrow{\mathcal{D}} V, \qquad n \to \infty,$$

with V κ-stable. If $\kappa > 2$,

$$\frac{1}{\sqrt{n}\sigma} \sum_{j=1}^{n} (X_i - \mathbf{E}X_\infty) \xrightarrow{\mathcal{D}} Z \sim N(0, 1).$$

Stationary Markov chain

KKS result

Let T_n be the first hitting time of n. $T_n \approx 2 \sum_{k=1}^{n} X_k - n$.

Theorem (Kesten & Kozlov & Spitzer 1975)

For $\kappa \in (0, 2)$,

$$n^{-1/\kappa}(T_n - A_n) \xrightarrow{\mathcal{D}} \kappa - \text{stable r.v.}$$

where $A_n \equiv 0$ if $\kappa < 1$, $A_n = nc_1$ if $\kappa > 1$.
For $\kappa > 2$

$$n^{-1/2}(T_n - nc) \xrightarrow{\mathcal{D}} N(0, 1).$$

Moreover, $n^{-\kappa}(W_n - B_n)$ also converges.

Perpetuity equation

$(A_n, B_n)_n$ iid random vectors, and X_0 a random variable independent of them. The stochastic recurrence equation is

$$X_{n+1} = A_{n+1}X_n + B_{n+1}.$$

The stationary solution should be

$$X_\infty = B_1 + A_1 B_2 + \ldots + A_1 A_2 \ldots A_n B_{n+1} + \ldots =: \sum_{n=0}^\infty \Pi_n B_{n+1}.$$

Satisfies the fixed point equation

$$X \stackrel{\mathcal{D}}{=} AX + B,$$

where (A, B) and X on the RHS are independent.
